

# 1 The matrices S and Q in SDC

Assume we have a given time-interval  $[T_0, T_1]$  and a set of collocation nodes  $\tau_m, m = 0, \dots, M$  with

$$T_0 \leq \tau_0 < \dots < \tau_M \leq T_1 \quad (1)$$

For Gauss-Lobatto quadrature,  $\tau_0$  and  $\tau_M$  will coincide with  $T_0$  and  $T_1$ , for Gauss-Legendre quadrature they won't.

## 1.1 Quadrature over the full interval

For a set of given nodes  $(\tau_j)_{j=0, \dots, M}$ , there is a unique set of weights  $q_m, m = 0, \dots, M$  such that the corresponding quadrature rule yields an approximation of the integral over  $[T_0, T_1]$  with maximum order  $2M - 2$  for Gauss-Lobatto,  $2M$  for Gauss-Legendre and  $2M - 1$  for Gauss-Radau. That is with

$$\mathbf{q} := (q_0, \dots, q_M) \in \mathbb{R}^{M+1} \quad (2)$$

we have

$$\int_{T_0}^{T_1} u(\tau) d\tau \approx \sum_{m=0}^M q_m u_m = \mathbf{q}^T \cdot \mathbf{u} =: \mathbf{I}(\mathbf{u}) \quad (3)$$

for

$$\mathbf{u} := (u_0, \dots, u_M) \in \mathbb{R}^{M+1} \text{ with } u_j \approx u(\tau_j), j = 0, \dots, M. \quad (4)$$

Denoting by  $l_m, m = 0, \dots, M$ , the Lagrangian polynomials with roots  $\tau_m$ , the weights  $q_m$  are given as

$$q_m = \int_{T_0}^{T_1} l_m(\tau) d\tau \quad (5)$$

## 1.2 Quadrature from left endpoint to a collocation node – Q

The Picard formula on which SDC is based reads for a point  $t$  in  $[T_0, T_1]$

$$u(t) = u(T_0) + \int_{T_0}^t f(u(\tau), \tau) d\tau. \quad (6)$$

Thus, the solution at some collocation node  $\tau_m$  is given by

$$u(\tau_m) = u(T_0) + \int_{T_0}^{\tau_m} f(u(\tau), \tau) d\tau. \quad (7)$$

To obtain a discrete version, we now define operators  $\mathbf{I}_0^m$  that provide an approximation of the integral over a part of the time interval  $[T_0, T_1]$ , namely

$$\mathbf{I}^m(\mathbf{u}) := \mathbf{q}_m^T \cdot \mathbf{u} = \sum_{j=0}^M q_{m,j} u(\tau_j) \approx \int_{T_0}^{\tau_m} u(\tau) d\tau, \quad m = 0, \dots, M. \quad (8)$$

**Remark 1.** If the left endpoint  $T_0$  coincides with the first collocation node  $\tau_0$ , we get  $\mathbf{I}_0^0 \equiv 0$ .

**Remark 2.** If the right endpoint  $T_1$  coincides with the last collocation node  $\tau_M$ , we have  $\mathbf{I} = \mathbf{I}_0^M$ , cf. (??), but otherwise the two operators are different.

The weights for the  $\mathbf{I}_0^m$  can be computed from the following consideration: Let  $p$  denote the uniquely determined interpolation polynomial through the points  $(\tau_m, u_m)$ , so that

$$p(\tau) = \sum_{m=0}^M u_m l_m(\tau) \quad (9)$$

where  $l_m$  are the Lagrangian polynomials as introduced above. Then, approximating

$$\int_{T_0}^{\tau_m} u(\tau) d\tau \approx \int_{T_0}^{\tau_m} p(\tau) d\tau \quad (10)$$

leads to weights

$$q_{m,j} := \int_{T_0}^{\tau_m} l_j(\tau) d\tau. \quad (11)$$

**Remark 3.** Because the  $l_j$  are polynomials of order  $M$ , the weights  $q_{m,j}$  can be exactly computed using a quadrature rule of order  $M + 1$ .

The matrix  $\mathbf{Q}$  is now defined as

$$\mathbf{Q} := \begin{bmatrix} \mathbf{q}_0 \\ \mathbf{q}_1 \\ \vdots \\ \mathbf{q}_M \end{bmatrix} \in \mathbb{R}^{M+1, M+1} \quad (12)$$

so that

$$\mathbf{Q}\mathbf{u} = \begin{pmatrix} \mathbf{I}^0(\mathbf{u}) \\ \mathbf{I}^1(\mathbf{u}) \\ \vdots \\ \mathbf{I}^M(\mathbf{u}) \end{pmatrix} \in \mathbb{R}^{M+1} \quad (13)$$

**Remark 4.** The iteration

$$\mathbf{u}^{k+1} = u(T_0)\mathbf{1} + \mathbf{Q}f(\mathbf{u}^k) \quad (14)$$

corresponds to a component wise iteration

$$u_m^k = u(T_0) + \mathbf{I}^m(f(\mathbf{u}^k)) \approx u(T_0) + \int_{T_0}^{\tau_j} f(u^k(\tau), \tau) d\tau, \quad m = 0, \dots, M \quad (15)$$

and thus to a discrete version of the Picard iteration.

**Remark 5.** For  $\tau_M < T_1$ , an approximation for  $u(T_1)$  can easily be obtained in every iteration by computing

$$u = u(T_0) + \mathbf{I}(f(\mathbf{u}^k)) = u(T_0) + \mathbf{q}^T \cdot f(\mathbf{u}^k) \approx u(T_0) + \int_{T_0}^{T_1} f(u(\tau), \tau) d\tau. \quad (16)$$

**Remark 6.** If  $T_0 = \tau_0$ , it is  $\mathbf{I}^0 \equiv 0$  and thus the first row in  $\mathbf{Q}$  consists of zeros. Iteration (??) thus never changes the first entry in  $\mathbf{u}$ , leading to

$$u_0^{k+1} = u(T_0) \quad (17)$$

for all  $k \geq 0$ .

### 1.3 Quadrature between two consecutive collocation nodes – S

For use within the sweeps of SDC, we also need approximations to the integral between two consecutive nodes, i.e. an operator

$$\mathbf{I}_{m-1}^m(\mathbf{u}) =: \mathbf{s}_m \cdot \mathbf{u} = \sum_{j=0}^M s_{m,j} u(\tau_j) \approx \int_{\tau_{m-1}}^{\tau_m} u(\tau) d\tau, \quad m = 1, \dots, M \quad (18)$$

As before, the weights can be computed as integrals over the Lagrangian polynomials  $l_j$ , that is

$$s_{m,j} = \int_{\tau_{m-1}}^{\tau_m} l_j(\tau) d\tau \quad (19)$$

Note that from (??) and (??) we immediately obtain the following identity

$$q_{m,j} = q_{0,j} + \sum_{j=1}^m s_{m,j} \Leftrightarrow \int_{T_0}^{\tau_m} l_j(\tau) d\tau = \int_{T_0}^{\tau_0} l_j(\tau) d\tau + \sum_{k=1}^m \int_{\tau_{k-1}}^{\tau_k} l_j(\tau) d\tau \quad (20)$$

and thus

$$\mathbf{q}_m = \mathbf{q}_0 + \sum_{j=1}^m \mathbf{s}_j \quad (21)$$

For  $\mathbf{q}_m$ ,  $m = 0, \dots, M$  given, we can thus compute the weights  $\mathbf{s}_m$ ,  $m = 1, \dots, M$  from

$$\mathbf{s}_0 := \mathbf{q}_0 \quad (22)$$

$$\mathbf{s}_1 = \mathbf{q}_1 - \mathbf{q}_0 \quad (23)$$

$$\mathbf{s}_2 = \mathbf{q}_2 - \mathbf{q}_0 - \mathbf{s}_1 = \mathbf{q}_2 - \mathbf{q}_1 \quad (24)$$

$$\mathbf{s}_3 = \mathbf{q}_3 - \mathbf{q}_0 - \mathbf{s}_1 - \mathbf{s}_2 = \mathbf{q}_3 - \mathbf{q}_2 \quad (25)$$

$$\vdots \quad (26)$$

where the definition of  $\mathbf{s}_0 := \mathbf{q}_1$  is for convenience. This allow to immediately state the following identity

**Lemma 1.** *For any  $1 \leq m \leq M$  it holds that*

$$\mathbf{I}^0 + \sum_{j=0}^{m-1} \mathbf{I}_j^{j+1}(\mathbf{u}) = \mathbf{I}^m(\mathbf{u}) \quad (27)$$

*Proof.* Use the identity  $q_j = s_j + q_{j-1}$  shown above and compute

$$\mathbf{I}^m(\mathbf{u}) = \mathbf{q}_m^T \cdot \mathbf{u} \quad (28)$$

$$= (\mathbf{s}_m + \mathbf{q}_{m-1})^T \cdot \mathbf{u} \quad (29)$$

$$= (\mathbf{s}_m + \mathbf{s}_{m-1} + \mathbf{q}_{m-2})^T \cdot \mathbf{u} \quad (30)$$

$$= \dots \quad (31)$$

$$= (\mathbf{s}_m + \dots + \mathbf{s}_1 + \mathbf{s}_0)^T \cdot \mathbf{u} \quad (32)$$

$$= \mathbf{s}_m^T \cdot \mathbf{u} + \dots + \mathbf{s}_1^T \cdot \mathbf{u} + \mathbf{s}_0^T \cdot \mathbf{u} \quad (33)$$

$$= \mathbf{I}_{m-1}^m(\mathbf{u}) + \dots + \mathbf{I}_0^1(\mathbf{u}) + \mathbf{I}^0(\mathbf{u}). \quad (34)$$

□

The matrix  $\mathbf{S}$  is now defined as

$$\mathbf{S} := \begin{bmatrix} \mathbf{s}_0 \\ \mathbf{s}_1 \\ \vdots \\ \mathbf{s}_M \end{bmatrix} \in \mathbb{R}^{M+1, M+1} \quad (35)$$

so that

$$\mathbf{S}\mathbf{u} = \begin{pmatrix} \mathbf{I}^0 \\ \mathbf{I}_0^1 \\ \mathbf{I}_1^2 \\ \vdots \\ \mathbf{I}_{M-1}^M \end{pmatrix} \in \mathbb{R}^{M+1} \quad (36)$$

when defining

$$\mathbf{I}_{j-1}^j(\mathbf{u}) := \mathbf{s}_j^T \cdot \mathbf{u}, \quad j = 1, \dots, M \text{ and } \mathbf{I}^0(\mathbf{u}) := \mathbf{s}_0^T \cdot \mathbf{u}. \quad (37)$$

## 2 Picard iteration

As shown in Remark ??, the matrix  $\mathbf{Q}$  can be used to define a discrete Picard iteration. The iteration can be equivalently formulated as a "sweep" over the nodes.

**Lemma 2.** *The node-by-node sweep*

$$u_m^{k+1} = u_{m-1}^{k+1} + \mathbf{I}_{m-1}^m(f(\mathbf{u}^k)), \quad m = 1, \dots, M \quad (38)$$

with initialization

$$u_0^{k+1} := u(T_0) + \mathbf{I}^0(f(\mathbf{u}^k)) \quad (39)$$

is equivalent to the full-system iteration (??).

*Proof.* For a  $0 \leq m \leq M$ , compute

$$u_m^{k+1} = u_{m-1}^{k+1} + \mathbf{I}_{m-1}^m(f(\mathbf{u}^k)) \quad (40)$$

$$= u_{m-2}^{k+1} + \mathbf{I}_{m-2}^{m-1}(f(\mathbf{u}^k)) + \mathbf{I}_{m-1}^m(f(\mathbf{u}^k)) \quad (41)$$

$$= \dots \quad (42)$$

$$= u_0^{k+1} + \sum_{j=0}^{m-1} \mathbf{I}_j^{j+1}(f(\mathbf{u}^k)) \quad (43)$$

$$= u(T_0) + \mathbf{I}^0(f(\mathbf{u}^k)) + \sum_{j=0}^{m-1} \mathbf{I}_j^{j+1}(f(\mathbf{u}^k)) \quad (44)$$

$$= u(T_0) + \mathbf{I}^m(f(\mathbf{u}^k)) \quad (45)$$

where the last identity used Lemma ?. This is now exactly the component-wise Picard iteration (?).  $\square$

**Remark 7.** Note that if the first node coincides with the left boundary, i.e.  $\tau_0 = T_0$ , then  $\mathbf{I}^0 \equiv 0$  and the initialization (??) simply sets  $u_0^{k+1} = u(T_0)$ .

**Remark 8.** The product  $\mathbf{I}_{m-1}^m(f(\mathbf{u}^k))$  in (??) corresponds to the scalar product

$$\mathbf{s}_m^T \cdot f(\mathbf{u}^k) = \sum_{j=0}^M s_j f(u_j^k) \quad (46)$$

In the object oriented implementation, this scalar product can be evaluated using the sum and scalar multiplication routine of the solution object, provided that if  $u$  is a solution object, so is  $f(u)$ .

### **3 SDC sweeps**
